

Subdomain Enumeration — cheat sheet

Automates subdomain discovery by running Subfinder, Assetfinder, and Sublist3r in sequence, then merging all results.

Step 1 — Install the Three Tools

```
# Subfinder
go install -v github.com/projectdiscovery/subfinder/v2/cmd/subfinder@latest

# Assetfinder
go install github.com/tomnomnom/assetfinder@latest

# Sublist3r
pip install sublist3r
```

Step 2 — Run

```
chmod +x subdomain_enum.sh
./subdomain_enum.sh example.com
# also accepts full URLs:
./subdomain_enum.sh https://example.com/anything
```

Step 3–5 — Three Tools, Different Sources

Tool	Data Sources	Best for
Subfinder	Cert transparency, Shodan, VirusTotal, APIs	Passive, fast, comprehensive
Assetfinder	DNS records, web crawl, related assets	Finding related domains
Sublist3r	Google, Bing, Yahoo, DNSdumpster, crt.sh	Search engine enumeration

Step 6 — Merge & Deduplicate

All three tool outputs are combined and deduplicated automatically with `sort -u`. You get one clean file with no duplicates.

Step 7 — Reading the Output

```
[+] Running Subfinder...      Found 43 subdomains
[+] Running Assetfinder...    Found 31 subdomains
[+] Running Sublist3r...      Found 27 subdomains

[*] Total unique subdomains: 61
[*] Results saved to: subdomains_example.com.txt
```

Open the results file and pipe into other tools:

```
cat subdomains_example.com.txt | httpx      # find live hosts
cat subdomains_example.com.txt | nmap ...   # port scan them
```

Key idea: no single tool finds everything — running all three and merging gives the best coverage. Subfinder usually finds the most, Assetfinder catches related assets the others miss.
