

The Harvester — cheat sheet

Passive OSINT tool for collecting emails and subdomains from Google, Bing, crt.sh, and HackerTarget.

Step 1 — Install & Run

```
pip install -r requirements.txt
python3 the_harvester.py -d example.com
```

Step 2 — Flags

Flag	Description	Example
-d	Target domain (required)	-d example.com
-s	Sources to use (default: all)	-s google,crt
-o	Save output to file	-o results.txt

Step 3 — Sources

Source	What it collects
google	Email addresses from Google search results
bing	Email addresses from Bing search results
crt	Subdomains from certificate transparency logs (crt.sh)
hackertarget	Subdomains from HackerTarget DNS lookup API

Step 4 & 5 — Reading Results

Emails found:

```
admin@example.com
info@example.com
john.doe@example.com
```

Subdomains found:

```
mail.example.com
vpn.example.com
dev.example.com
```

Emails feed into phishing simulation and credential guessing. Subdomains feed into further scanning.

Run Examples

```
# All sources
python3 the_harvester.py -d example.com

# Only cert transparency + bing
python3 the_harvester.py -d example.com -s crt,bing

# Save to file
python3 the_harvester.py -d example.com -o results.txt
```

Key idea: combine this with email-enum — use the harvester to find real email addresses and known subdomains, then use email-enum to guess additional addresses for people not yet found publicly.
