

WHOIS Lookup — cheat sheet

Pulls WHOIS registration data for one or more domains — registrar, dates, nameservers, and registrant email.

Step 1 — Install & Run

```
pip install -r requirements.txt
python3 whois_lookup.py example.com
```

Step 2 — Usage

```
# Single domain
python3 whois_lookup.py example.com

# Multiple domains
python3 whois_lookup.py example.com target.org

# Save to JSON
python3 whois_lookup.py example.com target.org -o results.json
```

Step 3 — What It Returns

Field	What it tells you
Registrar	Who the domain is registered with
Creation date	When the domain was first registered (age = trust signal)
Expiration date	When it expires — expiring soon = acquisition opportunity
Name servers	Hosting / DNS provider — reveals infrastructure
Registrant email	Contact email — useful for OSINT on the org
Country	Registrant country
DNSSEC	Whether the domain has DNSSEC enabled

Reading the Output

```
Domain      : example.com
Registrar   : GoDaddy
Created     : 1995-08-14
Expires     : 2025-08-13
Nameservers: ns1.example.com, ns2.example.com
Email       : admin@example.com
Country     : US
DNSSEC      : unsigned
```

A very young domain (days or weeks old) combined with suspicious content is a strong phishing indicator.

Key idea: domain age is one of the strongest signals. Phishing domains are almost always newly registered (under 30 days). Combine with the phishing-detector for URL risk scoring.
