

Password Auditor — cheat sheet

Analyzes a list of passwords from a dump or audit, grades each A–F, and generates a remediation report.

Step 1 — Run

```
# No pip install needed – pure Python 3
python3 password_auditor.py passwords.txt

# Show top N weakest
python3 password_auditor.py passwords.txt --worst 20

# Save report
python3 password_auditor.py passwords.txt -o report.txt
```

Step 2 — What Gets Checked Per Password

Check	What it catches
Length	Under 8 (fail), under 12 (weak), 12+ (good)
Character classes	Missing uppercase, lowercase, digits, symbols
Common passwords	Top 200 from rockyou / breach lists
Keyboard walks	qwerty, 12345, 1q2w3e, asdfgh
Repeated chars	aaa, 111, zzzzz
Dictionary words	password, admin, welcome, dragon
Leet speak	p4ssw0rd, @dm1n, s3cur3 — detected and penalized
Digit-only	123456, 19901225
Word+number	password1, admin123, football99
Shannon entropy	Bits of entropy based on character pool and length

Step 3 — Grading Scale

Grade	Score	Meaning
A	80-100	Strong — meets modern standards
B	65-79	Good — minor improvements suggested
C	50-64	Moderate — notable weaknesses
D	35-49	Weak — needs improvement
F	0-34	Critical — immediate reset required

Step 4 — Dataset Report

Grade Distribution:

A	#####		12%
B	#####		18%
C	#####		28%
D	#####		22%
F	#####		20%

Top weakness patterns:

1. Common password (41%)
2. Word + number suffix (28%)
3. Keyboard walk (19%)

Remediation: enforce 12+ char minimum, reject common patterns

Key idea: use this after a credential dump or during an internal audit. The dataset report's pattern analysis tells you what policy to enforce — if 40% of passwords end in a number, your policy needs a rule against it.
